- ▶ Six Ways to Get Help & Course Collaboration Leaders
- ▶ Moodle & assignments debrief
- ▶ Joining the class late? Please reach out to me.

# Base R: What Beginners Need to Know

## What is Base R?

- ▶ **Base R** refers to the core set of functions, data types, and utilities included with the default R installation.
- ▶ It provides essential tools for working with vectors, data frames, lists, and matrices, as well as basic **data manipulation**, **statistics**, and **plotting** functions.

## Alternatives to Base R

- ▶ **Tidyverse**: A collection of packages designed for more intuitive data manipulation and visualization. Syntax is often cleaner for larger data workflows. (**We will learn this next.**)
- ▶ **Data.table**: A faster alternative to Base R data frames, optimized for large datasets. (**Beyond scope of class.**)
- ▶ **Matrix-specific Packages**: For large numerical datasets, for efficient matrix operations. (**Beyond scope of class.**)

# Why Learn Base R?

- ▶ Provides a **strong foundation**: Most R packages build upon the principles of Base R, so understanding it helps you with advanced techniques.
- ▶ **Lightweight**: Base R functions are fast and simple for smaller or less complex tasks.
- ▶ **Always available**: Base R is built-in, meaning you don't need to install any additional packages.

## Some syntax and terminology (mostly a review)

- ▶ An R **object** can store different types of data, such as:
  - ▶ **Numbers** (e.g., 10, 3.14)
  - ▶ **Text** (e.g., "Hello", "R is fun!")
  - ▶ **Vectors** (e.g., a list of numbers or text)
  - ▶ **Data Frames** (e.g., tables of data)
- ▶ We assign values to objects using the `<-` operator or `=`.
  - ▶ Tip: `<-` is very much preferred, but `=` also works.
- ▶ R **functions** are commands that perform specific tasks in R.
  - ▶ A function takes *input* (called arguments) and returns *output*.
  - ▶ You can pass objects as inputs into functions to operate on them.
  - ▶ Some functions inspect objects by telling us info about it.

```
[1] "numeric"
```

# Overview of Data Frames in Base R

A data frame is a two-dimensional table-like structure that can hold **columns of different types** (e.g., numeric, character, and logical).

Each column in a data frame is a vector, and the length of each vector (number of rows) must be the same across all columns.

# Built-in Data Frames in R

We use a R package in base R called `datasets` to access built-in toy data frames.

## Viewing the Data Frame

Let's inspect the data frame `mtcars` by looking at the first 6 rows using the function `head()`:

|                   | mpg  | cyl | disp | hp  | drat | wt    | qsec  | vs | am |
|-------------------|------|-----|------|-----|------|-------|-------|----|----|
| Mazda RX4         | 21.0 | 6   | 160  | 110 | 3.90 | 2.620 | 16.46 | 0  | 1  |
| Mazda RX4 Wag     | 21.0 | 6   | 160  | 110 | 3.90 | 2.875 | 17.02 | 0  | 1  |
| Datsun 710        | 22.8 | 4   | 108  | 93  | 3.85 | 2.320 | 18.61 | 1  | 1  |
| Hornet 4 Drive    | 21.4 | 6   | 258  | 110 | 3.08 | 3.215 | 19.44 | 1  | 0  |
| Hornet Sportabout | 18.7 | 8   | 360  | 175 | 3.15 | 3.440 | 17.02 | 0  | 0  |
| Valiant           | 18.1 | 6   | 225  | 105 | 2.76 | 3.460 | 20.22 | 1  | 0  |

Let's look at the structure of the data frame using `str()`:

```
'data.frame':  32 obs. of  11 variables:
 $ mpg : num  21 21 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 ...
 $ cyl : num  6 6 4 6 8 6 8 4 4 6 ...
 $ disp: num  160 160 108 258 360 ...
 $ hp  : num  110 110 93 110 175 105 245 62 95 123 ...
 $ drat: num  3.9 3.9 3.85 3.08 3.15 2.76 3.21 3.69 3.92 3. ...
 $ wt  : num  2.62 2.88 2.32 3.21 3.44
```

## Column and Row Names

```
[1] "mpg"  "cyl"  "disp" "hp"   "drat" "wt"   "qsec" "vs"  
[11] "carb"
```

```
[1] "Mazda RX4"           "Mazda RX4 Wag"       "Datsun 7  
[4] "Hornet 4 Drive"     "Hornet Sportabout"   "Valiant"  
[7] "Duster 360"         "Merc 240D"           "Merc 230  
[10] "Merc 280"           "Merc 280C"           "Merc 450S  
[13] "Merc 450SL"         "Merc 450SLC"         "Cadillac  
[16] "Lincoln Continental" "Chrysler Imperial"   "Fiat 128  
[19] "Honda Civic"        "Toyota Corolla"      "Toyota Co  
[22] "Dodge Challenger"   "AMC Javelin"         "Camaro Z2  
[25] "Pontiac Firebird"   "Fiat X1-9"           "Porsche 9  
[28] "Lotus Europa"       "Ford Pantera L"      "Ferrari D  
[31] "Maserati Bora"      "Volvo 142E"
```

# Accessing Columns in Data Frames

**Like with matrices, we can use `[]` to designate a column.**

But it is not a good coding practice to use numbers within the brackets. If our data frame gets rearranged, our code would be wrong. Instead, we use column names as follows:

```
[1] "numeric"
```

```
[1] "data.frame"
```

## Accessing Rows in Data Frames

**We can also use brackets to get particular rows.** Note here, we need to put the row name before a comma. And it returns a data.frame.

```
[1] "data.frame"
```

## Subsetting Rows

We can also get multiple rows:

|               | mpg | cyl | disp | hp  | drat | wt    | qsec  | vs | am | gear |
|---------------|-----|-----|------|-----|------|-------|-------|----|----|------|
| Mazda RX4     | 21  | 6   | 160  | 110 | 3.9  | 2.620 | 16.46 | 0  | 1  | 4    |
| Mazda RX4 Wag | 21  | 6   | 160  | 110 | 3.9  | 2.875 | 17.02 | 0  | 1  | 4    |

## More Advanced Row Subsetting

Let's get all the Mercedes without having to type them out.

```
[1] FALSE FALSE FALSE FALSE FALSE FALSE FALSE TRUE TRUE  
[13] TRUE TRUE FALSE FALSE FALSE FALSE FALSE FALSE FALSE  
[25] FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE
```

|      |        | mpg  | cyl | disp  | hp  | drat | wt   | qsec | vs | am | gear | ca |
|------|--------|------|-----|-------|-----|------|------|------|----|----|------|----|
| Merc | 240D   | 24.4 | 4   | 146.7 | 62  | 3.69 | 3.19 | 20.0 | 1  | 0  | 4    |    |
| Merc | 230    | 22.8 | 4   | 140.8 | 95  | 3.92 | 3.15 | 22.9 | 1  | 0  | 4    |    |
| Merc | 280    | 19.2 | 6   | 167.6 | 123 | 3.92 | 3.44 | 18.3 | 1  | 0  | 4    |    |
| Merc | 280C   | 17.8 | 6   | 167.6 | 123 | 3.92 | 3.44 | 18.9 | 1  | 0  | 4    |    |
| Merc | 450SE  | 16.4 | 8   | 275.8 | 180 | 3.07 | 4.07 | 17.4 | 0  | 0  | 3    |    |
| Merc | 450SL  | 17.3 | 8   | 275.8 | 180 | 3.07 | 3.73 | 17.6 | 0  | 0  | 3    |    |
| Merc | 450SLC | 15.2 | 8   | 275.8 | 180 | 3.07 | 3.78 | 18.0 | 0  | 0  | 3    |    |

## Using \$ to Access Columns

**We can also use “data.frame.name\$” to refer to columns/variables.**

```
[1] 20.09062
```

## Creating a New Column

We can also use this approach to add columns to a data frame. In the example below, we create a new column `kpg` that converts miles per gallon (`mpg`) to kilometers per gallon.

|                   | <code>mpg</code> | <code>cyl</code> | <code>disp</code> | <code>hp</code> | <code>drat</code> | <code>wt</code> | <code>qsec</code> | <code>vs</code> | <code>am</code> |
|-------------------|------------------|------------------|-------------------|-----------------|-------------------|-----------------|-------------------|-----------------|-----------------|
| Mazda RX4         | 21.0             | 6                | 160               | 110             | 3.90              | 2.620           | 16.46             | 0               | 1               |
| Mazda RX4 Wag     | 21.0             | 6                | 160               | 110             | 3.90              | 2.875           | 17.02             | 0               | 1               |
| Datsun 710        | 22.8             | 4                | 108               | 93              | 3.85              | 2.320           | 18.61             | 1               | 1               |
| Hornet 4 Drive    | 21.4             | 6                | 258               | 110             | 3.08              | 3.215           | 19.44             | 1               | 0               |
| Hornet Sportabout | 18.7             | 8                | 360               | 175             | 3.15              | 3.440           | 17.02             | 0               | 0               |
| Valiant           | 18.1             | 6                | 225               | 105             | 2.76              | 3.460           | 20.22             | 1               | 0               |

# Reading and Writing Data Files

## .RData (or .Rda) files

- ▶ .RData files can store multiple R objects. Sometimes data files are stored as .rds files, which only store a single object.
- ▶ After loading, the objects contained in the .RData file will be available in your R environment with their original names.

## .csv files or .txt files

A common way to import external data into R is from a CSV file.

Use the `read.csv()` function.

For plain text files, use `read.table()` or `readLines()`:

# Tips

- ▶ File Paths: File paths can be absolute or relative.
  - ▶ Absolute paths specify the exact location on your computer.
  - ▶ Relative paths are relative to your current working directory in R.
  - ▶ **We set up R Studio so that it should be easy to use relative paths!**
- ▶ Working Directory:
  - ▶ Use `getwd()` to find your current working directory
  - ▶ Use `setwd("path/to/directory")` to change it.
  - ▶ **But we set up R Studio so that if you .Rproj is loaded, your current working directory is set.**
- ▶ Viewing Data: After reading a file, use `head(data)` to view the first few lines of your data frame.
- ▶ Handling Errors: If R can't read your file, check for typos in the file path and ensure the file format is correct.
